(Received on: 13-01-13; Revised \& Accepted on: 09-02-13)

#### Abstract

This paper presents a simple deterministic model of dysfunctions of eye- tracking. The model is formulated as a second order nonlinear ordinary differential equation, incorporating non Hookesien cubic restoring force. The equation is solved analytically by employing a perturbation technique with the nonlinear restoring force coefficient as the perturbation parameter. Jump phenomena in angular displacement, angular velocity were discussed for wide spectrum of parameter values. Identified the equilibrium points of the model equation and stability of equilibrium points is also discussed.

Key words: Pursuit Eye Tracking, Nonlinear Oscillations, Jump Phenomena.

## 1. INTRODUCTION

Dysfunctions [5, 10] in smooth pursuit eye movement are frequently encountered in schizophrenia patients [3], and also in some individuals with disorders of their central nervous system may be due to generic reasons [4]. The person suffering with such dysfunction would have to rotate the eye to track the signal which is coming from the periodically moving target [1],[2]. When the target motion is periodic the eye ball oscillations observed as a case study of undamped free oscillations [6]. This situation is modeled mathematically using a second order nonlinear ordinary differential equation of duffing type with a cubic non -Hooksian restoring force subject to non homogeneous initial conditions. An approximate solution of the modeled equation is obtained by employing a perturbation technique [9]. The perturbation parameter $(\varepsilon)$ is characteristic of the nonlinearity of the restoring force. The angular displacement versus dimension less time profiles, the angular velocity versus dimensionless time profiles and phase plane portraits are illustrated for wide spectra of the perturbation parameter ( $\varepsilon$ ), the initial angular displacement (a) and the initial angular velocity (b). A look at these illustrations shows the resonating character of both the angular displacement and angular velocity with the increase of initial data and increasing the coefficient of nonlinear restoring force, and spiral type of variations in the phase planes in the case of soft spring are discussed. The phenomenon of jump in dysfunction dynamic parameters angular displacement, angular velocity was discussed for wide spectrum of parameters and establishing the nonlinearity in the jump of dysfunction dynamic parameters using Lagrangian interpolation. Identified the equilibrium points of the model equation and stability of equilibrium points is also discussed.

$\alpha \quad: \quad$ The damping coefficient
k : Hooksian restoring constant
L : A nonlinear non hooksian restoring coefficient
A : peak to peak amplitude of the target moving periodically
$w_{d} \quad: \quad$ The frequency of the target

## 3. MATHEMATICAL MODEL EQUATION

The deterministic eye dynamics in the presence of a target which is moving periodically, a nonlinear differential equation, is given by [perspectives in biological dynamics and theoretical medicine]
$I \frac{d^{2} \phi}{d t^{2}}+\alpha \frac{d \phi}{d t}+k \phi-L \phi^{3}=A \cos \left(\omega_{d} t\right)$
$\phi(0)=\alpha, \phi^{\bullet}(0)=\beta$
where $\alpha$ and $\beta$ are the initial values of the angular displacement and initial angular velocity of the eye ball respectively.

In terms of the following non dimensional parameters,
$t=\frac{\tau}{\omega_{0}}, \frac{\phi}{\phi_{0}}=\psi, \frac{k}{I}=\omega_{0}^{2}, \frac{\omega_{d}}{\omega_{0}}=\Omega, \frac{\alpha}{I \omega_{0}}=2 \delta, \frac{\phi_{0}^{2} L}{I \omega_{0}^{2}}=\varepsilon, \frac{A}{I \omega_{0}^{2} \phi_{0}}=\Gamma$
$\phi(t)=\phi_{0} \psi\left(\frac{\tau}{\omega_{0}}\right), \quad \phi(0)=\phi_{0} \psi(0)$
$\alpha=\phi_{0} \psi_{0}, \frac{\alpha}{\phi_{0}}=a$
$\phi^{\bullet}(0)=\omega_{0} \phi_{0} \quad \psi^{\bullet}(0), \beta=\omega_{0} \phi_{0} b$
By using (3) equation (1) can be reduced to
$\varphi_{0} I \frac{d^{2} \psi}{d t^{2}}+\alpha \varphi_{0} \frac{d \psi}{d t}+k \varphi_{0} \psi-L \varphi_{0}{ }^{3} \psi^{3}=A \cos \left(\omega_{d} t\right)$
$\omega_{0}{ }^{2} \varphi_{0} I \frac{d^{2} \psi}{d \tau^{2}}+\alpha \varphi_{0} \omega_{0} \frac{d \psi}{d \tau}+k \varphi_{0} \psi-L \varphi_{0}{ }^{3} \psi^{3}=A \cos \left(\omega_{d} \frac{\tau}{\omega_{0}}\right)$
$\frac{d^{2} \psi}{d \tau^{2}}+2 \delta \frac{d \psi}{d \tau}+\psi-\varepsilon \psi^{3}=\Gamma \cos (\Omega \tau)$
with initial conditions $\psi(0)=a, \psi^{*}(0)=b$

The coefficient $\varepsilon$ signifies non Hooksian character of the nonlinear restoring force. This formulation signifies undamped free oscillations of dysfunctions in eye movement take $\delta=0, \Gamma=0$
The equation (4) reduces to $\frac{d^{2} \psi}{d \tau^{2}}+\psi-\varepsilon \psi^{3}=0$
with initial conditions $\quad \psi(0)=a, \psi(0)=\mathrm{b}$
The spring is soft (or) hard accordingly $\varepsilon$ is negative and positive respectively

## 4. ANALYTIC SOLUTION:

Let the $\psi(\tau)=\psi^{(0)}(\tau)+\varepsilon \psi^{(1)}(\tau)+\varepsilon^{2} \psi^{(2)}(\tau)+.$.

Substituting (8) in the equation (6) and collecting the like powers of $\varepsilon$ on both sides of equality we get the equations in the successive stages of approximation.

## 5. THE BASIC (OR) ZERO TH ORDER APPROXIMATION

In this approximation the equation to be solved is

$$
\begin{equation*}
\frac{d^{2} \psi^{(0)}}{d \tau^{2}}+\psi^{(0)}=0 \tag{11}
\end{equation*}
$$

With the initial conditions $\psi^{(0)}(0)=a, \quad \psi^{(0) \bullet}(0)=b$

This yields the solution is $\psi^{(0)}(\tau)=a \cos (\tau)+b \sin (\tau)$

## 6. THE FIRST ORDER APPROXIMATION

The equation for $\psi^{(1)}(\tau)$ is $\frac{d^{2} \psi^{(1)}}{d \tau^{2}}+\psi^{(1)}=(a \cos \tau+b \sin \tau)^{3}$
With initial conditions $\psi^{(1)}(0)=0, \psi^{\bullet(1)}(0)=0$
The solution of equation (14) satisfying the initial conditions in (15) is

$$
\begin{align*}
\psi^{(1)}(\tau)= & \frac{\left(a^{3}-3 a^{2} b\right)}{32} \cos \tau+\frac{9\left(b^{3}+5 a^{2} b\right)}{32} \sin \tau-\frac{\left(a^{3}-3 a^{2} b\right)}{32} \cos 3 \tau \\
& -\frac{\left(3 a^{2} b-b^{3}\right)}{32} \sin 3 \tau-\frac{\left(3 b^{3}+3 a^{2} b\right)}{8} \tau \cos \tau+\frac{\left(3 a^{3}+3 a b^{2}\right)}{8} \tau \sin \tau \tag{16}
\end{align*}
$$

Hence up to this order of approximation the angular displacement is given by

$$
\begin{align*}
& \psi(\tau)=\psi^{(0)}(t)+\varepsilon \psi^{(1)}(\tau)  \tag{17}\\
& \psi(\tau)=(a \cos \tau+b \sin \tau)+\frac{\varepsilon}{32}\left[\begin{array}{l}
\left(a^{3}-3 a^{2} b\right) \cos \tau+9\left(b^{3}+5 a^{2} b\right) \sin \tau-\left(a^{3}-3 a^{2} b\right) \cos 3 \tau \\
-\left(3 \mathrm{a}^{2} b-b^{3}\right) \sin 3 \tau-4\left(3 b^{3}+3 a^{2} b\right) \tau \cos \tau+4\left(3 a^{3}+3 a b^{2}\right) \tau \sin \tau
\end{array}\right] \tag{18}
\end{align*}
$$

And the angular velocity is given by

$$
\psi^{\bullet}(\tau)=(-a \sin \tau+b \cos \tau)+\frac{\varepsilon}{32}\left[\begin{array}{l}
-\left(a^{3}-3 a^{2} b\right) \sin \tau+9\left(b^{3}+5 a^{2} b\right) \cos \tau+3\left(a^{3}-3 a^{2} b\right) \sin 3 \tau  \tag{19}\\
-3\left(3 a^{2} b-b^{3}\right) \cos 3 \tau-4\left(3 b^{3}+3 a^{2} b\right)(\cos \tau-\tau \sin \tau) \\
+4\left(3 a^{3}+3 a b^{2}\right) \tau(\cos \tau+\sin \tau)
\end{array}\right]
$$

## 7. THE ANGULAR DISPLACEMENT VERSES TIME PROFILES FOR DIFFERENT VALUES OF PARAMETERS ARE GIVEN BELOW

Fig. 2: variation of angular displacement versus time for the nonlinear restoring coefficient $\varepsilon=0.001$, initial angular displacement $a=0.001$ and initial angular velocity $b=0.001$, For this parameter values the amplitude of angular displacement is not changing as time increases.

Fig. 3: variation of angular displacement versus time for the nonlinear restoring coefficient $\varepsilon=0.001$, initial angular displacement $\mathrm{a}=1$ and initial angular velocity $\mathrm{b}=1$. For this parameter values the amplitude of angular displacement is not changing as time increases.

Fig. 4: variation of angular displacement versus time for the nonlinear restoring coefficient $\varepsilon=0.001$, initial angular displacement $\mathrm{a}=10$ and initial angular velocity $\mathrm{b}=10$. For this parameter values the amplitude of angular displacement is increasing as time increases.

Fig. 5: variation of angular displacement versus time for the nonlinear restoring coefficient $\varepsilon=0.01$, initial angular displacement $a=0.001$ and initial angular velocity $b=0.001$, For this parameter values the amplitude of angular displacement is not changing as time increases.

Fig. 6: variation of angular displacement versus time for the nonlinear restoring coefficient $\varepsilon=0.01$, initial angular displacement $\mathrm{a}=1$ and initial angular velocity $\mathrm{b}=1$. For this parameter values the amplitude of angular displacement is increasing as time increases.

Fig. 7: variation of angular displacement versus time for the nonlinear restoring coefficient $\varepsilon=0.01$, initial angular displacement $a=10$ and initial angular velocity $b=10$. For this parameter values the amplitude of angular displacement is increasing rapidly as time increases.

## 8. PHASE PLANE PORTRAITS

The angular velocity versus angular displacement profiles (analytical phase plane portraits) are given for different values of parameter

9. JUMP PHENOMINA IN PEAK TO PEAK AMPLITUDE OF DYSFUNCTION DYNAMIC PARAMETERS -ANGULAR DISPLACEMENT AND ANGULAR VELOCITY
The dysfunction dynamical parameters angular displacement and angular velocity are simulated in the time interval [ 0,100 ] using the analytical solution of the model (18), (19) and using the software MATLAB. For different values of the parameters in the model such as initial angular displacement, initial angular velocity and coefficient of nonlinear restoring force are taken at different levels and using the analytical solution of the model. Jump in peak to peak amplitude of The dysfunction dynamical parameters angular displacement and angular velocity calculated as shown in the Fig (11).

Fig. 11: The figure shows the jump phenomena of dysfunction dynamic parameter i.e ( the angular displacement)

## 10. JUMP PHENOMINA IN PEAK TO PEAK AMPLITUDE OF DYSFUNCTION DYNAMIC PARAMETERS -ANGULAR DISPLACEMENT:

The Nonlinear restoring coefficient $\varepsilon$ is taken in three levels $(0.001,0.01,0.1,1)$ together with no initial angular displacement and varying the initial angular velocity( b),Then The jump in peak to peak amplitude in angular displacement is function of initial angular velocity (b). The graph of Lagrangian interpolated polynomial is given for each case, by taking the values of parameter (b) taken on $x$-axis and the corresponding jump in peak to peak amplitude taken on Y-axis.

Table: 1

| $\varepsilon$ | a | b | Minimum value of peak to peak <br> amplitude | Maximum value of peak to peak <br> amplitude | Jump in peak to peak <br> amplitude |

## 13. STABILITY ANALYSIS

The differential equation
$\frac{d^{2} \psi}{d \tau^{2}}+\psi-\varepsilon \psi^{3}=0$
The above differential equation divided into two first order differential equations
$\frac{d \psi}{d \tau}=y$
$\frac{d y}{d \tau}=\varepsilon \psi^{3}-\psi$

The system has the following four equilibrium states (i)-(iii) resulting from
$\frac{d \psi}{d \tau}=y=0 ;$
$\frac{d y}{d \tau}=\varepsilon \psi^{3}-\psi=0$
$\mathrm{E}_{1}$ : state in which both angular displacement angular velocity are zero

$$
\begin{equation*}
\bar{\psi}=0 ; \bar{y}=0 \tag{24}
\end{equation*}
$$

$\mathrm{E}_{2}$ : $\quad$ The state in which only the angular displacement is not equal to zero
And angular velocity is equal to zero $\bar{\psi}= \pm(1 / \sqrt{ } \varepsilon) ; \bar{y}=0$

## 14. STABILITY OF THE EQUILIBRIUM STATES

15. Stability of the Equilibrium State $E_{1}$ :

$$
\bar{\psi}=0 ; \bar{y}=0
$$

We consider slight deviations $u_{1}(\tau)$ and $u_{2}(\tau)$ over the steady state
$(\bar{\psi}, \bar{y})$

$$
\begin{align*}
& \psi=\bar{\psi}+u_{1}(\tau)  \tag{26}\\
& y=\bar{y}+u_{2}(\tau) \tag{27}
\end{align*}
$$

Where $u_{1}(\tau)$ and $u_{2}(\tau)$ are small so that terms other than the first order can be neglected.
By substituting (2.26) and (2.27) in (2.21) and (2.22) we get
$\frac{d u_{1}}{d \tau}=\bar{y}+u_{2}$
$\frac{d u_{2}}{d \tau}=\varepsilon\left[(\bar{\psi})^{3}+3(\bar{\psi})^{2} u_{1}+3(\bar{\psi}) u_{1}^{2}+u_{1}^{3}\right]-(\bar{\psi})-u_{1}$
By neglecting products and second and higher powers of $u_{1}$ and $u_{2}$, we get
$\frac{d u_{1}}{d \tau}=u_{2} ; \quad \frac{d u_{2}}{d \tau}=-u_{1}$
Whose roots are $\pm \mathrm{i}$, both the roots are complex. Hence the steady state is unstable. Further from (30) and (31) we get
$u_{1}=u_{10} \cos \tau+u_{20} \sin \tau ;$
© 2013, IJMA. All Rights Reserved
$u_{2}=-u_{10} \sin \tau+u_{20} \cos \tau$
Where $u_{10}, u_{20}$ are initial values of $u_{1}, u_{2}$ respectively and the solution curves are shown in Figures 28 to 31 and the conclusions are presented below.
16. Stability of the equilibrium states $\mathbf{E}_{2}, \mathbf{E}_{3}: \bar{\psi}= \pm \frac{1}{\sqrt{\varepsilon}} ; \bar{y}=0$

By substituting (2.26) and (2.27) in (2.21) and (2.22) we get
$\frac{d u_{1}}{d \tau}=\bar{y}+u_{2}$
$\frac{d u_{2}}{d \tau}=\varepsilon\left[(\bar{\psi})^{3}+3(\bar{\psi})^{2} u_{1}+3(\bar{\psi}) u_{1}^{2}+u_{1}^{3}\right]-(\bar{\psi})-u_{1}$
By neglecting products and second and higher powers of $u_{1}$ and $u_{2}$, the corresponding linearised perturbed equations are
$\frac{d u_{1}}{d \tau}=u_{2}$
$\frac{d u_{2}}{d \tau}=2 u_{1}$
Whose roots are $\pm \sqrt{ } 2$ both the roots are real and opposite. Hence the steady state is unstable .The solutions of equations (36) and (37) are given by
$u_{1}(\tau)=\left(\frac{u_{10}+\frac{u_{20}}{\sqrt{2}}}{2}\right) e^{\sqrt{2} \tau}+\left(\frac{u_{10}-\frac{u_{20}}{\sqrt{2}}}{2}\right) e^{-\sqrt{2} \tau}$ and $u_{2}(\tau)=\left(\frac{u_{10}+\frac{u_{20}}{\sqrt{2}}}{\sqrt{2}}\right) e^{\sqrt{2} \tau}-\left(\frac{u_{10}-\frac{u_{20}}{\sqrt{2}}}{\sqrt{2}}\right) e^{-\sqrt{2} \tau}$

Fig. 28: variation of $u_{1}(\tau)$ and $u_{2}(\tau)$ versus dimensionless time at equilibrium $E_{1}$

Fig. 29: Trajectories of perturbed angular displacement $u_{1}(\tau)$ and angular velocity $u_{2}(\tau)$ at $\quad E_{1}$

Fig. 30: variation of $u_{1}(\tau)$ and $u_{2}(\tau)$ versus dimensionless time at equilibrium $E_{3}$ and $E_{4}$

Fig. 31: Trajectories of perturbed angular displacement $u_{1}(\tau)$ and angular velocity $u_{2}(\tau)$ at $E_{2}$ and $E_{3}$

## CONCLUSIONS

(1) The resonating character in both the dysfunction dynamic parameters (angular displacement, angular velocity) is increasing with increasing of initial data and the coefficient of nonlinear restoring force( $\varepsilon$ ).
(2) The Lagrangian interpolating patterns showing that the jump in peak to peak amplitude is Linear for lower values of initial data and lower values of non linear restoring coefficient, the nonlinearity appears in early stages with increase of parameters (a,b, $\varepsilon$ ).
